

FLOW AVERAGING TUBE AND METHOD OF USING SAME**CROSS-REFERENCE TO RELATED APPLICATIONS**

[0001] This is the first application filed for the present invention.

FIELD OF THE INVENTION

[0002] The present invention relates to a flow measuring device and more particularly, the present invention relates to a probe for measuring fluid flow at a plurality of locations with the data being averaged to ascertain fluid flow with greater precision.

BACKGROUND OF THE INVENTION

[0003] Flow measurement technology is quite mature in the art as is evinced by the innumerable patents granted for this field.

[0004] Generally, pitot type tubes are employed for making flow determinations. An example is found in United States Patent No. 6,164,143, issued December 26, 2000, to Evans. The disclosure relates to a tip flow barrier for a pitot type flow meter. There is provided a barrier for preventing undesirable fluid flow between a tip portion of the probe and the inside of a pipe within which it is placed.

[0005] Tanis, in United States Patent No. 4,961,349, issued October 9, 1990, provides a flow meter operating on a hydraulic grade differential determined by fluid pressure in a reduced cross sectional area of the meter and the fluid through the conduit in which the meter is positioned.

[0006] United States Patent No. 4,154,100, issued to Harbaugh et al., May 15, 1979, relates to a method and

apparatus for stabilizing the flow coefficient for pitot-type flow meters with a downstream facing port. In the device, the system employs an averaging pitot-type flow meter which provides a flow deflector with sharply contoured edges to fix the location at which a boundary layer separation occurs over a broad range of laminar and turbulent flow conditions.

[0007] Although the arrangement is a flow averaging arrangement, the device is still dependent upon position of the low pressure ports on the downstream side of the body together with shaping and positioning the downstreams such as the boundary layer separation points cannot become reattached.

[0008] Mahoney et al., in United States Patent No. 5,773,726, issued June 30, 1998, provides a flow meter of the pitot variety with a temperature sensor. The flow meter is designed for mass flow measurement and provides a body for insertion into a confined conduit. The body provides separated plenums with openings provided in the body which expose the plenums to high and low fluid pressure during fluid flow through the conduit. A temperature sensor is disposed within the body of the probe.

[0009] In United States Patent No. 4,703,661, issued November 3, 1997 to Evers, there is provided a differential pressure flow probe which provides leading edges having dynamic pressure apertures and a sensor for static pressure with one of the sensors formed in the rear edge of the body, the sensor aperture is located in the wake of the body with the front surfaces swept back from a forward tip and provided with detachment ridges for the lateral

detachment of the incident fluid flow without subsequent reattachment.

[0010] In this art, there is a great concern in the previously proposed arrangements for disruption of the fluid flow and more particularly a separation of the fluid as it contacts the flow meter. To this end, numerous designs have been configured in the prior art to present a more aerodynamic flow meter with a probe together with other ancillary features such as temperature sensors, *inter alia*.

[0011] It would be desirable if there were a flow averaging probe which was not susceptible to probe shape or positioning within a duct. In reality, it is evident that fluid flow is often required for measurement in irregularly shaped conduits. Such geometrical irregularity presents complex flow patterns, turbulence and other observations in the fluid flow which can adversely effect an accurate measurement. The prior art arrangements were effected by such conditions and required position, reattachment or non reattachment of the separated fluid lines among a host of other difficulties. The present invention seeks to overcome these limitations and provide effective apparatus and measurement system for measuring fluid flow within a conduit.

SUMMARY OF THE INVENTION

[0012] One object of the present invention is to provide improved fluid flow meter of the pitot-type incorporating flow averaging together with a method of effecting use of such a flow meter.

[0013] In accordance with a further object of one embodiment of the present invention there is provided a flow averaging probe for measuring fluid flow, comprising:

an elongate probe;

a plurality of apertures disposed on the probe for receiving impact pressure of fluid flow therethrough;

sensor means adjacent the apertures for sensing the flow caused by impact pressure;

transmitter means for transmitting sensed data from the sensors; and

signal processing means for processing transmitted data.

[0014] It has been found that by positioning a sensor within or in line with the probe body, which probe body has a plurality of spaced apart apertures, more accurate readings can be obtained with the probe when the same is in contact with a fluid flow. Generally speaking, in the prior art the sensors were not disposed directly in contact with the pressure front, but in representative designs, the sensors were positioned in a low pressure zone of the probe typically where reattachment of the lamina occurred.

[0015] As an example, it has been found that the apertures may have a large diameter, an example of which may be 0.125 inches along the length of the upstream impact surface of probe.

[0016] Conveniently, the electronics for the probe may be encased in an explosive proof housing. The transmitter may be of the thermal dispersion type (RTD) and signal processor may be an analog or digital microprocessor.

[0017] A further object of one embodiment of the present invention is to provide a flow averaging probe for measuring fluid flow in a conduit, comprising in combination:

a conduit for transporting a fluid;

an elongate hollow probe releasably connected within the conduit;

a plurality of apertures disposed on the probe for receiving fluid flow therethrough;

sensor means proximate the apertures for sensing accumulated fluid flow;

transmitter means for transmitting sensed data from the sensors;

signal processing means for processing transmitted data; and

discharge means for discharging fluid sensed by the sensor means and of the probe.

[0018] The conduit will typically carry a gas for measuring flow and the conduit can be found in any conduit system carrying a gas such as heating ventilation and air conditioning (HVAC), variable air volume (VAV) applications among others well appreciated by those skilled in the art.

[0019] In a further object of one embodiment of the present invention there is provided a method of measuring fluid flow in a conduit, comprising:

providing a probe having a hollow elongate body with a plurality of apertures therethrough and sensor means proximate the apertures, the apertures for receiving fluid therethrough;

positioning the probe within a fluid stream to be measured;

collating individual fluid streams from the apertures within the probe;

activating the sensor means by fluid entering the apertures to obtain data generated by a collated stream; and

averaging obtained data to determine a representative flow rate.

[0020] Generally speaking, by retaining sensors within the body of the probe, successful results have been achieved when this feature is combined with apertures being spaced apart equidistantly or substantially equidistantly from one another for the collection of individual datum. The spacing will depend on the environment in which the probe is used and the needs of the user. As a particularly convenient feature, several of the units set forth herein can be grouped or inter connected and the data along a pipe line can be subsequently globally averaged to provide a particularly accurate flow result over a broad distance of the conduit. In terms of materials of which the probe may be made, it will be appreciated by those skilled in the art that the material will be selected to not be reactive with the fluid within which it will be disposed for a measurement and preferred materials would include, for example, stainless steel, ABS plastic, high impact polystyrene, polyvinylchloride, etc.

[0021] In respect of the sensors, these may comprise sensors of the type thermal, turbine, venturi, nozzle, oriface plate, variable area, paddle wheel, target,

coriolis, vortex shedder, ultrasonic, magnetic, Doppler, time of flight, propeller, laser, etc.

[0022] Having thus generally described the invention, reference will now be made to the accompanying drawings illustrating preferred embodiments.

BRIEF DESCRIPTION OF THE DRAWINGS

[0023] Figure 1 is an exploded view of one embodiment of the probe according to the present invention;

Figure 2 is a longitudinal cross-sectional view along line 22 of Figure 1;

Figure 3 is a view of the probe arrangement *in situ*; and

Figure 4 is a view of the probe in an alternate embodiment.

[0024] Similar numerals denote similar elements.

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENT

[0025] Referring now to the Figures, numeral 10 globally denotes the probe as shown in the example. The probe 10 includes a tube 12 which is elongate and hollow and includes a plurality of apertures 14 extending along the length thereof and in communication with the hollow interior of the tube 12. The apertures are equidistantly or otherwise preferably spaced from one another and allow communication from the exterior of the tube 12 to the interior thereof as illustrated in Figure 2 where gas flows through the apertures 14 to within the tube 12. The

terminal end 16 of tube 12 includes a solid end 18 which may receive a threaded member 20 in order to fasten the overall probe 10 into position as shown in Figure 3 and discussed hereinafter in greater detail.

[0026] Disposed within the interior of the tube 12 is a sensor 22 which is coaxially positioned within a sensor window and protection device 24. Optionally, a seal, typically in the form of an O-ring 26 locates the sensor window within the tube 12 so that it is positioned correctly as shown in Figure 2. The sensor window 24 may include a seating 28 to receive O-ring 26. Sensor window 24 includes an aperture 30 extending therethrough to facilitate sensing of any fluid coming within the vicinity of the arrows designated by numeral 32. A bushing 33 is threaded and received within a top portion of tube 12. This is more clearly illustrated in Figure 2. The bushing 33 also has a top threaded segment and a hex nut 34 to remediate the threaded portion. This facilitates a connection with a meter for monitoring a gas flow. Such a meter is shown in Figures 3 and 4 and represented by numeral 36. As is illustrated, all of the individual components are effectively positioned in a coaxial relationship and within the probe body 12. This is a particularly beneficial design feature since the key elements of the structure are protected within the body of the probe tube 12.

[0027] In terms of suitable materials, the choice for tube body 12 will completely depend upon the nature of the fluid in which the probe is inserted. In some instances it may be adequate to use suitable plastics such as HIPS, PVC, HDPE, and PVF *inter alia*. In situations where organic vapors are present, the use of synthetic materials may not

be appropriate. In this instance, various metals may be incorporated into the body as will be appreciated by those skilled in the art.

[0028] Figure 3 depicts the probe within a fluid conduit 38. Illustrated in the flow patterns of the fluid within the probe.

[0029] Figure 4 illustrates a further embodiment of the probe 10 in which the probe is positioned within fluid conduit 38 directly within the fluid flow pattern of the conduit 38. As illustrated in the example, the fluid then travels through the probe 10, is metered by meter 36 and is returned by conduits 40 and 42 back into the fluid stream. Generally speaking, in use gas flow enters the probe tube 12 through apertures 14 as indicated in Figure 2. The gas travels down the centre of tube 12 through sensor insert 24 and contacts the sensor 22 disposed therein. Once the gas flow is sensed the gas is discharged through openings 30 in insert 24 as indicated by arrows 32. The sensed gas is then discharged through openings 44 in tube 12. Once discharged through openings 44, the fluid is then returned to the environment from which it was initially sampled.

[0030] As the illustrations depict, the sensor is substantially proximate the apertures and effectively senses accumulated fluid flow that enters the apertures 14. This is eventually sensed and metered. In this manner, by the nature of the design of the probe a plurality of fluid streams are effectively amalgamated once they are accumulated and thus an average fluid flow is established from a variety of locations at different points of the lamina. In this manner, aberrations or inconsistencies in the flow due to localized eddy currents or other fluid

spoiler situations do not affect the reading of fluid passing through the probe. This is in marked contrast to the arrangements in the prior art where the probes measured pressure and simply averaged the pressure over a certain distance. The present arrangement averages flow and therefore renders, overall, the irregularities in the flow to a minimum in view of the averaging.

[0031] Although embodiments of the invention have been described above, it is not limited thereto and it will be apparent to those skilled in the art that numerous modifications form part of the present invention insofar as they do not depart from the spirit, nature and scope of the claimed and described invention.
